Lecture 13: 02/22/2022
Lecturer: Xiaorui Sun

Scribe: Sriman Cherukuru

## 1 Last Lecture's Review

Last Lecture: Graph decomposition

- Utilization of nice properties on good edges (intra-component)
- Upper bound on the number of bad edges (inter-component)

This Lecture: Graph sparsification (Edge, Vertex sparsification)

- Preserve important properties of the original graph
- Bounding the size of sparsified graph for computation efficiency

## 2 Graph sparsification

### 2.1 Edge sparsification

$$
G=(V, E) \rightarrow H=\left(V, E^{\prime}\right)
$$

Such that: property on $H \approx$ property on $G$, and $|E| \ll|E|$. Eg., Spanning forest for graph connectivity property.

### 2.2 Vertex sparsification

$$
G=(V, E), \text { (terminal set) } T \subset V \rightarrow H=\left(V^{\prime}, E^{\prime}\right)
$$

Such that: $T \subset V^{\prime}$, property on $T$ in $H \approx$ property on $T$ in $G,\left|V^{\prime}\right| \ll|V|,\left|E^{\prime}\right| \ll|E|$. Eg., weighted graph for distance property.

3 VERTEX SPARSIFICATION FOR MIN-CUT PROPERTY

## 3 Vertex sparsification for min-cut property

### 3.1 Problem

Given $G=(V, E), T \subset V$, construct a vertex sparsifier $H=\left(V^{\prime}, E^{\prime}\right)$ such that: $T \subset V^{\prime}$, and for all partitions of $T$ into $\left(T^{\prime}, T \backslash T^{\prime}\right)$ :

$$
\operatorname{mincut}_{H}\left(T^{\prime}, T \backslash T^{\prime}\right)=\operatorname{mincut}_{G}\left(T^{\prime}, T \backslash T^{\prime}\right)
$$

With additional parameter of threshold $c$ :

$$
\begin{aligned}
& \quad \text { If } \operatorname{mincut}_{G}\left(T^{\prime}, T \backslash T^{\prime}\right) \leq c \text {, then } \operatorname{mincut}_{H}\left(T^{\prime}, T \backslash T^{\prime}\right)=\operatorname{mincut}_{G}\left(T^{\prime}, T \backslash T^{\prime}\right) \text {. } \\
& \text { If mincut }\left(T^{\prime}, T \backslash T T^{\prime}\right)>c \text {, then mincut }\left(T^{\prime}, T \backslash T^{\prime}\right)>c \text {. }
\end{aligned}
$$

### 3.2 The algorithm

Definition 1 (Cut containment set) $A$ set of edges $E^{\prime}$ in $G$ is called a cut containment set if $\forall\left(T^{\prime}, T \backslash T^{\prime}\right)$ with $\operatorname{mincut}_{G}\left(T^{\prime}, T \backslash T^{\prime}\right) \leq c, \exists$ such a min-cut with edges $C$ and $C \subset E^{\prime}$.

Definition 2 (Intersecting-all-mincut set (old definition)) Given $G=(V, E)$, terminal set $T \subset V$ and threshold $c$, we say a set of edges $F$ in $G$ is a set of edges intersecting all min terminal cuts if $\forall\left(T^{\prime}, T \backslash T^{\prime}\right)$ with mincut $G\left(T^{\prime}, T \backslash T^{\prime}\right) \leq c, \exists$ such a min-cut with edges $C$ and $C \cap F=\emptyset$.

Definition 3 (Intersecting-all-mincut set (new definition)) Given $G=(V, E)$, terminal set $T \subset V$ and threshold $c$, we say a set of edges $F$ in $G$ is a set of edges intersecting all min terminal cuts if after removing $F$ from $G, \forall\left(T^{\prime}, T \backslash T^{\prime}\right)$ with mincut ${ }_{G}\left(T^{\prime}, T \backslash T^{\prime}\right) \leq c$, no connected component in $G \backslash F$ contains all the edges of a terminal min-cut.

Theorem 4 For vertex sparsification with respect to the min-cut property with threshold parameter $c$, there exists a sparsifier of size $|T| \cdot c^{O(c)}$.
(Can be improved to $|T| \cdot c^{3} \cdot \log ^{4} n$.)
Suppose we have a cut containment set $E^{\prime}$, we can construct a vertex sparsifier $H$ from $E^{\prime}$ in the following way:

- Remove edges in $E^{\prime}$ from $G$, breaking $G$ into several connected components.
- Shrink each connected component into 1 super-vertex in $H$.
- Connect vertices in $H$ with corresponding edges in $E^{\prime}$.
- If terminal vertices $u, v$ are merged into the same connected component (thus the terminal nodes are lost in $H$ ), add $u, v$ as vertices in $H$, connect each with $c+1$ parallel edges to the super-vertex corresponding to the connected component they're in. (There were no min-cut of size $\leq c$ between them in $G$.)

Resulting $H$ has number of edges (and vertices) $\leq\left|E^{\prime}\right|+|T| \cdot(c+1)$. Next, we need to upper-bound size of $E^{\prime}$.

Claim 5 Given $G, T, c, \exists E^{\prime} s t .\left|E^{\prime}\right|=|T| \cdot c^{O(c) .}$
Proof idea: recursively build $E^{\prime}$ using intersecting-all-set $F$ :

- Initialize $E^{\prime}=\emptyset$.
- Find intersecting-all-set $F_{c}$ in $G$ for given $T=T_{0}$ and $c$.
- Remove all edges in $F_{c}$ from $G$, add them to $E^{\prime}$, and add endpoints of edges in $F_{c}$ to terminals:
$G \leftarrow G \backslash F_{c}, E^{\prime} \leftarrow E^{\prime} \cup F_{c}, T_{1} \leftarrow T_{0} \cup\left\{u, v \mid(u, v) \in F_{c}\right\}$.
- Continue to find intersecting-all-set $F_{c-1}$ with updated $G$ and $T_{1}$, until $c=1$.
- Return $E^{\prime}$ (which is $\cup_{i=1}^{c} F_{c}$ ).

Claim 6 Given $G, T, c$, the intersecting-all-set $F_{c}$ is of size $\left|F_{c}\right| \leq|T| \cdot c$. (Each terminal vertex is incident to at most c edges that are on any qualifying min terminal cut.)
Proof of Claim 5 by induction:
Base case: $\left|F_{c}\right| \leq|T| \cdot c$.
Step 1: $\left|T_{1}\right| \leq|T|+2\left|F_{c}\right| \leq(1+2 c) \cdot|T|=O(c) \cdot|T|$, and $\left|F_{c-1}\right| \leq\left|T_{1}\right| \cdot c=O\left(c^{2}\right) \cdot|T|$.
General induction step: $\left|T_{i}\right| \leq\left|T_{i-1}\right|+2\left|F_{c-i+1}\right|=O\left(c^{i}\right) \cdot|T|,\left|F_{c-i}\right|=O\left(c^{i+1}\right) \cdot|T|$. Finally, $\left|F_{1}\right|=O\left(c^{c}\right) \cdot|T|$.
$\left|E^{\prime}\right|=\left|\cup_{i=1}^{c} F_{c}\right|=c^{(c)} \cdot|T|_{o}$.
