

CS 401 Homework 4

State all necessary assumptions clearly.
Show all the steps and give complete answers.
Please type or write your answers legibly.

Submit via Gradescope. Remember to associate page numbers of your solution PDF to question numbers.

- Chapter 5, Exercise 1
- Coin Changing Problem.
 - For an arbitrary denomination set $\{d_1, d_2, \dots, d_k\}$, give an algorithm to optimally solve (using the fewest number of coins) the coin-changing problem studied in class. That is, give an algorithm to make up v value using the fewest number of coins. The Bellman equation for this problem is given on slide 40-41 of "06DynamicProgrammingI.pdf". (Note: the c_i on the slide should be d_i .) Your algorithm should calculate the fewest number of coins to make up value v . Can you solve in space complexity $\theta(v)$?
 - Give the algorithm to print out the set of coins in the optimal solution. For example, if the denomination is the US denomination and $v = 19$, you should print out $\{1, 1, 1, 1, 5, 10\}$.
- Suppose you have a business which caters to Chicago and St. Louis. Each month, you can choose to either run your business from an office in Chicago, or from an office in St. Louis. In month i , you incur an operating cost of C_i if you run the business out of Chicago, and a cost of S_i if you instead run the business out of St. Louis. Each time you decide to switch between cities between two consecutive months, you incur a moving cost of M . Given a sequence of n months, a plan is a sequence of n locations (each one equal to either Chicago or St. Louis) such that the i^{th} location indicates the city in which you will be based in the i^{th} month. The cost of a plan is the sum of the operating costs for each of the n months, plus a moving cost M for each time you switch cities. The plan can begin in either city.
Your task is as follows: Given a value for M and sequences $(C_1; C_2; \dots; C_n)$ and $(S_1; S_2; \dots; S_n)$, give an efficient dynamic programming algorithm which returns the cost of an optimal plan for the n months in question.
- Let $G = (V, E)$ be a directed graph with nodes v_1, v_2, \dots, v_n . We say that G is an ordered graph if it has the following properties. (i) Each edge goes from a node with a lower index to a node with a higher index. That is, every directed edge has the form (v_i, v_j) with $i < j$. (ii) Each node except v_n has at least one edge leaving it. That is, for every node $v_i, i = 1, 2, \dots, n - 1$, there is at least one edge of the form (v_i, v_j) . The length of a path is the number of edges in the path.
Given an ordered graph G , find the length of the longest path that begins at v_1 and ends at v_n . Use a dynamic programming approach. What is the time complexity of your solution?
- For the sequence alignment problem, modify the code on page 282 to also produce (output) the actual alignment that gives the optimal value of the alignment.
